(Received November 6, 2000)

We discuss the anisotropies of the Hamiltonian and the wave-function in an $S = 1/2$ distorted diamond chain. The ground-state phase diagram of this model is investigated using the degenerate perturbation theory up to the first order and the level spectroscopy analysis of the numerical diagonalization data. In some regions of the obtained phase diagram, the anisotropy of the Hamiltonian and that of the wave-function are inverted, which we call *inversion phenomenon*; the Néel phase appears for the XY-like anisotropy and the spin-fluid phase appears for the Ising-like anisotropy. Three key words are important for this nature, which are frustration, the trimer nature, and the XXZ anisotropy.

KEYWORDS: spin chain, quantum phase transition, degenerate perturbation theory, frustration, trimer

1. Introduction

In quantum spin chains, a value of the anisotropy of the XXZ type interaction is an important factor regarding to what kind of the ground state is realized. In a case of an $S = 1/2$ XXZ chain, for instance, the Ising-like anisotropy brings about the Néel or ferromagnetic ground state, and the XY-like anisotropy brings about the spin-fluid (SF) ground state (see Fig.1(a)). In a case of an $S = 1$ XXZ chain, the Ising-like anisotropy also brings about the Néel or ferromagnetic ground state (see Fig.1(b)). However, this relation between the anisotropy and the ground state is sometimes broken for frustrated systems. In fact, a novel nature in the ground-state phase diagram has been found by Okamoto and Ichikawa.¹ That is, this relation is inverted in an $S = 1/2$ distorted diamond (DD) chain³⁻⁵ with the XXZ type interaction. Namely, the SF state appears for the Ising-like anisotropy in some regions of the phase diagram of the ground state, and the Néel state appears for the XY-like anisotropy (see Fig.1(c)). This inversion between the anisotropy of the Hamiltonian and that of the wave-function in the ground state is called the *inversion phenomenon*. From the viewpoint of the quantum statistical physics, this phenomenon is novel and exotic. It is found by one of the present authors (K.O.) that the inversion phenomenon also appears in an $S = 1/2$ trimerized XXZ chain with the next-nearest-neighbor interaction.²

In this paper, we elucidate the origin of the inversion phenomenon. We discuss the generalized DD chain model with the three kinds of the anisotropy parameters sketched in Fig.2. The Hamiltonian is

$$\mathcal{H} = J_1 \sum_j \{ \mathbf{S}_{3j-1} \cdot \mathbf{S}_{3j}(\Delta_1) + \mathbf{S}_{3j} \cdot \mathbf{S}_{3j+1}(\Delta_1) \} + J_2 \sum_j \mathbf{S}_{3j+1} \cdot \mathbf{S}_{3j+2}(\Delta_2)$$

Fig. 1. Schematic diagrams of the relation between the ground state and anisotropy for (a) a simple $S = 1/2$ XXZ chain, (b) a simple $S = 1$ XXZ chain, and (c) a DD chain for certain parameter sets. Here, Δ denotes the anisotropy (see Eq.(2)), and ferro, SF, and Haldane denote the ferromagnetic state, the spin-fluid state, and Haldane state, respectively.

$$+ J_3 \sum_j \mathbf{S}_{3j} \cdot \mathbf{S}_{3j+2}(\Delta_3), \quad (1)$$

where

$$\mathbf{S}_i \cdot \mathbf{S}_j(\Delta) \equiv S_i^x S_j^x + S_i^y S_j^y + \Delta S_i^z S_j^z, \quad \Delta > 0, \quad (2)$$

and J_1 denotes the intra-trimer coupling, and J_2 and J_3 the inter-trimer couplings. All the couplings are supposed to be antiferromagnetic ($J_1, J_2, J_3 > 0$). Okamoto and Ichikawa¹ discussed the case of $\Delta_1 = \Delta_2 = \Delta_3$. We use the generalized version to investigate the relation between the anisotropy parameter and the inversion phenomenon. Hereafter we consider a case, where $J_1 \gg J_2, J_3$.

2. Phase diagram

Let us discuss the ground state of the Hamiltonian Eq.(1) using the degenerate perturbation theory^{4,6,7} (DPT) up to the first order. First, we consider a $J_2 = J_3 = 0$ case which is merely a three-spin problem. The ground states of the j -th trimer are

$$|\uparrow_j\rangle \equiv \frac{1}{\sqrt{2+\lambda^2}} (|\uparrow\downarrow\downarrow\rangle - \lambda |\uparrow\uparrow\uparrow\rangle + |\downarrow\uparrow\uparrow\rangle) (S_{\text{tot}}^z = 1/2), \quad (3)$$

*E-mail : toku@stat.phys.titech.ac.jp

†E-mail : kokamoto@stat.phys.titech.ac.jp

Fig. 2. A sketch of the DD chain: solid lines, wavy lines, and dotted lines denote J_1 , J_2 , and J_3 coupling bond, respectively.

$$|\downarrow_j\rangle \equiv \frac{1}{\sqrt{2+\lambda^2}} (|\uparrow\downarrow\downarrow\rangle - \lambda|\downarrow\uparrow\downarrow\rangle + |\downarrow\downarrow\uparrow\rangle) \quad (S_{\text{tot}}^z = -1/2), \quad (4)$$

where $|\uparrow\downarrow\rangle$ denotes $|\uparrow\rangle_{3j-1} \otimes |\uparrow\rangle_{3j} \otimes |\downarrow\rangle_{3j+1}$, and λ is a constant

$$\lambda = \frac{\Delta_1 + \sqrt{\Delta_1^2 + 8}}{2} > \sqrt{2} \quad (\Delta_1 > 0). \quad (5)$$

Expectation values of the z -component of the spin are

$$\langle \uparrow_j | S_{3j\pm 1}^z | \uparrow_j \rangle = -\langle \downarrow_j | S_{3j\pm 1}^z | \downarrow_j \rangle = \frac{\lambda^2}{2(\lambda^2 + 2)} > 0, \quad (6)$$

$$\langle \uparrow_j | S_{3j}^z | \uparrow_j \rangle = -\langle \downarrow_j | S_{3j}^z | \downarrow_j \rangle = -\frac{\lambda^2 - 2}{2(\lambda^2 + 2)} < 0. \quad (7)$$

An eigenstate of N -trimer system is a tensor product of an eigenstate of the j -th trimer Hamiltonian. Since the ground states of a trimer are doubly degenerate, the ground states $|\Psi\rangle$ of N -trimer system are 2^N -fold degenerate and they are

$$|\Psi\rangle = \bigotimes_j |\psi_j\rangle, \quad |\psi_j\rangle = |\uparrow_j\rangle \text{ or } |\downarrow_j\rangle. \quad (8)$$

Next, we consider the $J_1 \gg J_2, J_3$ case, where J_2 and J_3 terms can be treated as perturbations. As far as we consider only the first-order corrections of the perturbations, we regard $|\Psi\rangle$ as a basis of a whole Hilbert space. It is convenient to introduce the pseudo-spin operator T_j with $T_j = 1/2$, by which $|\uparrow_j\rangle$ and $|\downarrow_j\rangle$ are expressed as $T_j^z = 1/2$ and $T_j^z = -1/2$ states, respectively. The original spin operators can be represented by the pseudo-spin operators:

$$S_{3j\pm 1}^x \equiv -\frac{2\lambda}{2+\lambda^2} T_j^x, \quad S_{3j\pm 1}^y \equiv -\frac{2\lambda}{2+\lambda^2} T_j^y, \quad (9)$$

$$S_{3j\pm 1}^z \equiv \frac{\lambda^2}{2+\lambda^2} T_j^z, \quad (10)$$

$$S_{3j}^x \equiv \frac{2}{2+\lambda^2} T_j^x, \quad S_{3j}^y \equiv \frac{2}{2+\lambda^2} T_j^y, \quad (11)$$

$$S_{3j}^z \equiv \frac{2-\lambda^2}{2+\lambda^2} T_j^z, \quad (12)$$

within the reduced basis. By straightforward calculations, the first-order correction with respect to J_2 and J_3 can be obtained as

$$\mathcal{H}_{\text{eff}} = \sum_j [J_{\text{eff}}^{\perp} (T_j^x T_{j+1}^x + T_j^y T_{j+1}^y) + J_{\text{eff}}^z T_j^z T_{j+1}^z], \quad (13)$$

where

$$J_{\text{eff}}^{\perp} = \frac{4\lambda(\lambda J_2 - 2J_3)}{(2+\lambda^2)^2}, \quad (14)$$

$$J_{\text{eff}}^z = \frac{\lambda^2 \{ \lambda^2 \Delta_2 J_2 - 2(\lambda^2 - 2)\Delta_3 J_3 \}}{(2+\lambda^2)^2}. \quad (15)$$

In Eq.(13), constant terms are omitted. This effective model is nothing but the one-dimensional spin-1/2 XXZ model. The XXZ model has three kinds of the ground states depending on the anisotropy: the ferromagnetic state, the SF state, and the Néel state. The ferromagnetic state in the T -picture corresponds to the $M_s/3$ ferrimagnetic state in the S -picture, where M_s is the saturation magnetization. Thus, the ground state of the original system is obtained from $J_{\text{eff}}^{\perp}$ and J_{eff}^z as follows.

$$\begin{aligned} J_{\text{eff}}^z < 0 \text{ and } |J_{\text{eff}}^z| > |J_{\text{eff}}^{\perp}| &\implies \text{ferrimagnetic state} \\ |J_{\text{eff}}^z| < |J_{\text{eff}}^{\perp}| &\implies \text{spin-fluid state} \\ J_{\text{eff}}^z > |J_{\text{eff}}^{\perp}| &\implies \text{Néel state} \end{aligned}$$

From the above inequalities, the phase diagram of the ground state with respect to three variables, Δ_1 , Δ_2 , and Δ_3 , can be obtained. The examples of the phase diagram are shown in Figs.3-8. Figures 3-5 are examples of the case in which the anisotropy parameters, Δ_1 , Δ_2 , and Δ_3 , are Ising-like. Figures 6-8 are examples of the case of the XY -like anisotropy parameters. Although the phase diagrams in a $\Delta_1 \neq 1$ case are not shown in this paper, the inversion phase also appears in that case. From Figs.3-8, it is clear that the inversion phases generally appear. Only in the cases of $\Delta_1 = 1, \Delta_2 = \Delta_3$, however, the inversion phases do not appear.

As a numerical check, we have also performed the numerical diagonalization using the Lanczos method and the level spectroscopy analysis.⁸⁻¹¹ We found that the numerical results are in good agreement with the results of the perturbation theory as shown in Figs.3-8.

3. Discussion

Let us discuss the ground-state phase diagram of the DD chain qualitatively. First, we consider a case where $\Delta_2, \Delta_3 > 1$. We note that the following discussions are qualitatively independent of Δ_1 . We discuss a correlation of neighboring trimers. Figure 9(a) shows a case where the two trimers are neighboring each other with $|\uparrow_j\rangle$ and $|\uparrow_{j+1}\rangle$. Figure 9(b) shows a case where they are neighboring with $|\uparrow_j\rangle$ and $|\downarrow_{j+1}\rangle$. The couplings J_2 is frustrated for Fig.9(a) since all the interactions are anti-ferromagnetic. Thus, we can consider that the situation of Fig.9(a) is stable for larger J_3 , while it is unstable for larger J_2 . On the other hand, the coupling J_3 is frustrated for Fig.9(b). Thus, we can also consider that the situation of Fig.9(b) is stable for larger J_2 , and unstable for larger J_3 . Of course, we did not mention that the phase boundary is $J_2 = J_3$ because its slope will depend on the values of anisotropies, as is expected from Eqs.(6)-(7). We obtain the qualitative sketch of the phase diagram shown in Fig.10(a); the area of $J_2 < J_3$ is the ferrimagnetic phase and that of $J_2 > J_3$ is the Néel phase.

Next, we discuss a case of $\Delta_2, \Delta_3 < 1$. The ordering effect of the couplings J_2 and J_3 are weak, because the Δ_2 and Δ_3 are XY -like. Therefore, a whole area of the J_2 - J_3 phase diagram where $J_2, J_3 \ll J_1$ will be the SF state (see Fig.10(b)). Comparing Fig.10 with Figs.3-8, we can see that the above discussions hit the point.

Let us proceed to the inversion phase. For Figs.4-5 and Figs.7-8, the inversion phase appears in an area $J_1 \gg J_2 \sim J_3$ where the trimer nature is still conspic-

uous, and J_2 and J_3 strongly compete with each other. We present an intuitive explanation in this competitive area. The interaction along the z -direction is stronger for the Ising-like case, by which the system is well-ordered to the Néel state in usual cases. However, the ordered state undergoes more energy loss in this area due to the competition between J_2 and J_3 . Thus, the spins are going to lie in the XY plane to avoid this energy loss, which brings about the disordered SF phase. A similar explanation holds for the XY -like case. The spins are going to lie in the XY -plane in usual cases, which corresponds to the SF state. In our case, since the energy loss due to the competition between J_2 and J_3 is serious, the spins are going to be pointed along the z -direction. Then, the ordered state (Néel or ferrimagnetic state) is realized. Another possible mechanism to avoid the energy loss due to the competing interactions is to form a singlet dimer pair. This mechanism is well known for the $S = 1/2$ chain with the next-nearest-neighbor interactions.^{12,13} However, the formation of the singlet dimer pair is irreconcilable with

Fig. 7. A phase diagram for $J_1 = 1, \Delta_1 = 1, \Delta_2 = 0.6, \Delta_3 = 0.2$. Solid lines denote the DPT result, and dots denote the numerical result.

Fig. 8. A phase diagram for $J_1 = 1, \Delta_1 = 1, \Delta_2 = 0.2, \Delta_3 = 0.6$. Solid lines denote the DPT result, and dots denote the numerical result.

Fig. 9. Schematic diagrams for the cases where two trimers are neighboring each other with (a) $|\uparrow\uparrow_j\rangle$ and $|\uparrow\uparrow_{j+1}\rangle$, and (b) $|\uparrow\uparrow_j\rangle$ and $|\downarrow\downarrow_{j+1}\rangle$. The shadow denotes a frustrated pair of spins.

the trimer nature. Therefore, the dimer phase does not appear for $J_1 \gg J_2, J_3$, where the trimer nature is conspicuous. In fact, we have found that the dimer phase appears in the regime $J_1 \sim J_2 \sim J_3$.¹⁴ Thus, we have intuitively explained why the inversion phenomenon appears in this area.

Thereby, it seems that the origin of the inversion phe-

nomenon is frustration, the trimer nature, and the XXZ anisotropy. In addition, the above discussion can also predict the location of the inversion phase. The inversion phase in Fig.4 is located on the upper left side, compared to that in Fig.5. This is because of the magnitude relation between Δ_2 and Δ_3 as explained in the following. In the above discussion, only the couplings J_2 and J_3 are considered as the ordering effect. However, not only J_2 and J_3 , but also Δ_2 and Δ_3 govern the orders. When $\Delta_2 > \Delta_3$, the Néel state area becomes wider in Fig.4, and the inversion phase is located on the upper left side. On the other hand, the ferrimagnetic state area becomes wider in Fig.5 because $\Delta_2 < \Delta_3$; this helps for the role of J_3 . Comparing Figs.7-8, we can also develop a similar discussion. The inversion phase is the Néel phase in Fig.7, and it is the ferrimagnetic phase in Fig.8. When J_2 and Δ_2 (J_3 and Δ_3) are relatively strong in comparison with J_3 and Δ_3 (J_2 and Δ_2), the more stable state is Fig.10(b) (Fig.10(a)). Thus, the Néel ordering effect is stronger for Fig.7, and the ferrimagnetic phase appears for Fig.8. We can interpret that the Néel phase (the ferrimagnetic phase) is selected as the inversion phase in Fig.7 (Fig.8).

The phase diagrams of the cases of Fig.3 and Fig.6 are remarkable. The inversion phase does not appear in these phase diagrams. The result of the analytical calculation indicates that the inversion phases are always absent when $\Delta_1 = 1$ and $\Delta_2 = \Delta_3$. The physical reason of the absence of the inversion phenomenon has not been understood yet.

Finally, we consider the origin of the inversion phenomenon in view of the effective model, Eqs.(13)-(15). The effective coupling constants $J_{\text{eff}}^{\perp}$ and $J_{\text{eff}}^{\parallel}$ are constructed of the subtraction of the terms proportional to J_2 and J_3 . Of course, the subtraction comes from the competition between couplings J_2 and J_3 . It can be manifestly expected that this subtraction causes the inversion between the anisotropy of the original model and that of the effective model. For instance, we discuss the case of $\Delta_1 = 1$, where $J_{\text{eff}}^{\parallel}/J_{\text{eff}}^{\perp} = (\Delta_2 J_2 - \Delta_3 J_3)/(J_2 - J_3)$. When $J_2 \gg J_3$, we see $J_{\text{eff}}^{\parallel}/J_{\text{eff}}^{\perp} \sim \Delta_2$ and $J_{\text{eff}}^{\parallel} > 0$. Meanwhile, when $J_2 \ll J_3$, it becomes $J_{\text{eff}}^{\parallel}/J_{\text{eff}}^{\perp} \sim \Delta_3$ and $J_{\text{eff}}^{\parallel} < 0$. Thus, we obtain the schematic phase diagram Fig.10. This agrees with the result of the previous qualitative discussion. On the other hand, when $J_2 \sim J_3$,

$J_{\text{eff}}^{\parallel}/J_{\text{eff}}^{\perp}$ can be Ising-like (XY-like) in spite of the XY-like (Ising-like) Δ_2 and Δ_3 . Here the subtraction plays a crucial role.

4. Conclusion

In this paper, we investigate the phase diagram of the ground state of the DD chain with the XXZ type interaction using the degenerate perturbation theory as well as the level spectroscopy analysis of the numerical diagonalization data. The obtained phase diagrams indicate that the inversion phase is stable to various sets of anisotropies. Our discussion suggests that frustration, the trimer nature and the XXZ type interaction are necessary for the inversion phenomenon. In fact, it has been found in the $S = 1/2$ trimerized XXZ chain with the next-nearest-neighbor interactions,² and also in the $S = 1/2$ frustrated three-leg ladder with the XXZ anisotropy.¹⁵ Therefore, we conclude that the inversion phase may appear in the phase diagram of the ground state for models with these three key words. Unfortunately, real materials corresponding to the above models have not been found yet. However, our prediction of this interesting phenomenon may become a motivation of searching or synthesizing the corresponding materials.

5. Acknowledgments

We would like to express our appreciation to Prof. Takashi Tonegawa and Prof. Masaki Oshikawa for stimulating discussions. For the numerical diagonalization, we used the package program TITPACK ver.2 developed by Prof. Hidetoshi Nishimori, to whom we are grateful. The present work has been supported in part by a Grant-in-Aid for Scientific Research (C) (No.14540329) from the Ministry of Education, Culture, Sports, Science and Technology.
